Introduction to Seismic Data Processing

Seismic data processing encompasses a series of methodical steps designed to enhance signal quality, suppress noise, and produce a coherent image of the subsurface. Raw seismic data, recorded during surveys, often contain numerous artifacts and distortions stemming from source irregularities, propagation effects, and environmental noise. Effective processing aims to mitigate these issues through a sequence of well-established techniques.

Key objectives include:

- Improving signal-to-noise ratio (SNR)
- Correcting for geometric and propagation effects
- Enhancing resolution of geological features
- Facilitating accurate interpretation

The ultimate goal of seismic data processing is to produce a seismic volume or section that faithfully represents subsurface structures for exploration and development decisions.

Fundamental Components of Seismic Data Processing

Seismic data processing can be broadly categorized into several interconnected stages:

- Data Preparation and Organization
- Data Editing and Quality Control
- Statics Correction
- Deconvolution
- Velocity Analysis and Normal Moveout (NMO) Correction
- Multiple Attenuation
- Stacking
- Migration
- Post-Processing Enhancements

Each stage addresses specific issues within the seismic data, cumulatively steering raw recordings toward a geologically meaningful image.

Data Preparation and Organization

The initial phase involves organizing the raw data into a suitable format for processing. This includes:

- Data Sorting: Arranging data into common midpoint (CMP) gathers, common shot, or common receiver formats.
- Metadata Compilation: Ensuring all relevant parameters (e.g., shot locations, receiver positions, acquisition parameters) are correctly documented.
- Data Conversion: Converting raw data into standard formats compatible with processing software.

Proper organization is critical as it sets the foundation for subsequent corrections and enhancements.

Data Editing and Quality Control

Before applying advanced processing techniques, data must be scrutinized:

- Visual Inspection: Identifying noisy traces, spikes, or equipment malfunctions.
- Trace Editing: Removing or correcting problematic traces to prevent contamination of the seismic image.
- Statistical Analysis: Quantifying noise levels and data consistency.
- Filtering: Applying preliminary filters to suppress high-frequency noise or low-frequency drifts.

Quality control ensures that artifacts are minimized and that the data are suitable for detailed processing.

Statics Correction

Statics correction addresses the time shifts introduced by near-surface irregularities, such as topography variations and weathered layers. These effects cause seismic waves to arrive earlier or later than expected, distorting the true subsurface image.

Types of statics corrections include:

- Refraction Statics: Correct for delays caused by low-velocity near-surface layers using refraction measurements.
- Residual Statics: Fine-tune corrections based on residual time shifts observed after initial corrections.

- Surface Consistency: Ensuring statics corrections are coherent across the survey area.

Effective statics corrections significantly improve the continuity of seismic reflections and enhance subsequent processing steps.

Deconvolution

Deconvolution aims to compress the seismic source wavelet and remove the effects of the seismic system's response. Raw seismic signals are convoluted with the source wavelet, which can obscure true geological reflections.

Types of deconvolution:

- Predictive Deconvolution: Suppresses multiples and reverberations, sharpening primary reflections.
- Statistical Deconvolution: Removes random noise, enhancing signal clarity.
- Sparse-Spike Deconvolution: Achieves maximum resolution by approximating the reflectivity series with sparse spikes.

Goals of deconvolution:

- Shortening the wavelet to improve vertical resolution
- Enhancing reflection continuity
- Simplifying subsequent velocity analysis

Deconvolution is critical for resolving thin beds and complex stratigraphy.

Velocity Analysis and Normal Moveout (NMO) Correction

Velocity analysis determines the seismic wave velocity within the subsurface, essential for accurate positioning of reflections.

Process overview:

- Velocity Picking: Interpreting semblance plots to identify the optimal stacking velocity.
- NMO Correction: Adjusting traces in CMP gathers to align reflections horizontally, compensating for the apparent travel-time differences caused by offset.

Key points:

- Accurate velocity models are vital for correct stacking and migration.
- Velocity analysis often involves iterative refinement, especially in complex geology.

This stage ensures that reflections are coherently stacked, increasing signal strength and resolution.

Multiple Attenuation

Seismic multiples are unwanted reflections that have undergone multiple reflections within the subsurface, often masking primary signals.

Techniques for multiple suppression:

- Surface-Related Multiple Elimination (SRME): Uses data-driven methods to predict and subtract multiples.
- Radon Transform-Based Methods: Differentiate multiples from primaries based on moveout characteristics.
- Wavefield Extrapolation: Models wave propagation to identify and remove multiples.

Effective multiple attenuation enhances the clarity of primary reflections, crucial for accurate interpretation.

Stacking

Stacking combines multiple seismic traces (e.g., CMP gathers) to enhance signal quality:

- Stacking Process: After applying NMO correction, traces are summed or averaged.
- Purpose: Amplifies coherent reflections while reducing random noise.
- Types of stacking:
- Linear Stack: Simple summation.
- Weighted Stack: Assigns weights based on semblance or other criteria.
- Importance: Provides a first-pass image of the subsurface, serving as the basis for migration.

Optimized stacking is fundamental for producing high-quality seismic sections.

Migration

Migration is a sophisticated process that repositions seismic reflections to their correct spatial locations, accounting for dipping layers and complex structures.

Types of migration:

- Kirchhoff Migration: Integrates data along diffraction surfaces; suitable for moderate complexities.
- Finite-Difference Migration: Numerically solves wave equations; handles complex geology better.
- Pre-Stack Migration: Uses data before stacking; preserves amplitude and phase information.
- Post-Stack Migration: Applied after stacking; improves imaging of complex structures like faults.

Goals of migration:

- Correct positional inaccuracies caused by dipping layers
- Collapse diffractions for clearer imaging

Background and Development of UBC 94 Seismic Provisions

Historical Context and Motivation

The early 1990s marked a period of increased awareness about earthquake risks, particularly after devastating events such as the 1985 Mexico City earthquake and the 1994 Northridge earthquake. These incidents underscored the necessity for robust building codes that could mitigate structural failures and safeguard human life. The UBC, first introduced in 1927, underwent multiple revisions, culminating in the 1994 edition that integrated advanced seismic design methodologies.

The primary motivation behind UBC 94 was to establish a unified, scientifically grounded set of seismic provisions that could be adopted across various jurisdictions in the United States and Canada. The goal was to standardize seismic design practices, improve structural safety, and reduce economic losses due to earthquake damage.

Development Process and Stakeholder Involvement

The development of UBC 94 involved collaboration among structural engineers, seismologists, code officials, and industry stakeholders. The process incorporated:

- Review of recent seismic research and data
- Analysis of past earthquake performances
- Incorporation of probabilistic seismic hazard assessments
- Testing and validation of design methodologies

This collaborative approach ensured that UBC 94 reflected current scientific understanding and practical engineering considerations.

Technical Foundations of UBC 94 Seismic Design

Seismic Hazard Analysis

At the core of UBC 94's seismic provisions is a rigorous hazard analysis framework, which estimates the likelihood of seismic events at specific locations. This involves:

- Seismic hazard maps that depict ground motion parameters such as peak ground acceleration (PGA)
- Site-specific assessments considering soil types, topography, and geological factors
- Use of probabilistic seismic hazard analysis (PSHA) to quantify the probability of exceedance of certain ground motion levels over a building?s lifespan

This foundation informs the seismic design category assigned to each site, influencing the stringency of design criteria.

Seismic Design Categories (SDCs)

UBC 94 classifies buildings into different Seismic Design Categories (SDCs), ranging from A (least critical) to F (most critical), based on:

- Seismic hazard level
- Occupancy importance
- Building use and function

These categories dictate the minimum requirements for structural design, detailing, and materials, ensuring that critical facilities receive higher levels of seismic resistance.

Design Ground Motion and Load Calculations

UBC 94 specifies the calculation of design base shear (V), which represents the lateral force a structure must resist during an earthquake. The process involves:

- Determining the Seismic Design Category
- Calculating the spectral response acceleration (Ss and S1 values)
- Applying the response spectrum method to compute the fundamental period (T) of the structure
- Using the formula $V = C_s \times W$, where C_s is the seismic response coefficient and W is the building?s weight

This approach ensures that structures are designed to withstand forces consistent with the seismic hazard at their location.

Structural System Requirements

UBC 94 emphasizes the importance of selecting appropriate structural systems based on the building's seismic risk. Key requirements include:

- Use of ductile materials like reinforced concrete and steel
- Detailing practices that allow energy dissipation and prevent brittle failures
